Third-Party Military Interventions, Conflict, Government Repression, and Human Rights

Maya Mikelson *

University of California, Berkeley

August 7, 2026

Abstract: This paper investigates the impact of third-party military interventions on human rights and government repression. The paper argues that interventions intensify human rights abuses by prolonging conflict and encouraging actors to increase repression post-conflict because the cost of conflict recurrence is higher. Using UCDP data on intrastate armed conflict and military interventions and V-Dem measures of physical integrity rights and human rights, the analysis accounts for non-random intervention. Because interventions select for certain conflict characteristics that are also correlated with human rights and repression, a Bayesian endogenous treatment effects model is used to control for the non-random choice of where countries and international organizations intervene. After controlling for selection bias, military intervention remains linked to lower human rights protection and increased state repression in both the short term (1 year) and medium term (5 years) post-conflict.

Keywords— Military intervention, intrastate conflict, government repression, human rights, conflict intensity, Bayesian selection model, selection bias

1 Introduction

The number of intrastate conflicts has risen from 21 in 2021 to 38 in 2024, part of a new trend of increasing conflicts that had otherwise been relatively flat since they fell at the end of the 20th century. Over the same period from 2021 to 2024, the number of intrastate conflicts with foreign troops dropped from 26 to 19 (Council on Foreign Relations, 2023). Since 2010, one-sided and non-state violence has increased both in terms of actors responsible and the number of deaths. For one-sided violence, in 2010, there were 23 actors responsible for 3,700 deaths, but in 2024, there were 49 actors responsible for 13,900 civilian deaths. For non-state violence, there were 32 conflicts causing 8,700 deaths in 2010 and 74 conflicts resulting in 17,500 deaths in 2024, although this is a decline from its peak in 2017 (Davies et al., 2025). Given these increases in conflicts and deaths that occurred simultaneously with a decreased international presence in civil conflicts, it is important to understand when and how peacekeeping operations minimize or stop conflicts and deaths.

Following the end of the Cold War, the distribution of types, frequency, and severity of civil war shifted. Civil wars during the Cold War were predominantly irregular wars with a high-capacity state fighting against low-capacity rebels due to aid from the US and USSR. After the Cold War, there was an increase in conventional civil war, where both rebels and the government have high capacity, and symmetric non-conventional civil war, where both sides have low capacity. Much of the work investigating the frequency of civil wars, ignores the shift in how wars were fought. The type of civil war has implications for what kind of peacekeeping and conflict prevention are most effective (Kalyvas and Balcells, 2010). Sambanis and Doyle have found that UN peacekeeping is more effective in states where it supports sovereignty and peacebuilding rather than undermines it, and the goals of the peacekeeping are aligned with the context of the situation (Sambanis and Doyle, 2011). However, much of the work investigating peacekeeping does not analyze the motivations of the conflict or the type beyond a few that control for the presence of ethnic divisions.

2 Literature Review

2.1 Peacekeeping During Civil War

Peacekeeping tends to select for more severe conflicts. After the Cold War, Gilligan and Stedman find that UN peacekeepers are more likely to be sent to civil wars with higher numbers of deaths. They also show that a country's power and region affect the probability of UN peacekeeping. The UN is less likely to send interventions to countries with strong armies. For the UN to intervene in Asia requires more deaths than in Africa, and an intervention in Africa requires more deaths than in Europe (Gilligan and Stedman, 2003). Gaibulloev et al. aim to identify what causes demand for both UN and non-UN peacekeeping. They find that non-UN peacekeeping missions have become more common since the early 2000s. These missions that do not involve the UN tend to be driven by trade relationships, protecting foreign direct investment, and regional proximity. UN peacekeeping missions tend to be driven by considerations of the global public benefits. The US and Japan contribute the most to UN peacekeeping and the US and UK contribute the most to non-UN peacekeeping (Gaibulloev, Sandler and Shimizu, 2009), which leaves uncertainty about how the structure of peacekeeping will shift after the US' withdrawal from international affairs in recent years.

Recent research has found that during civil wars, increased numbers of military UN peacekeepers are associated with reductions in battlefield violence and containment of conflict, but police and observer peacekeepers do not have the same effect (Hultman, 2010; Beardsley and Gleditsch, 2015). Beardsley and Gleditsch use georeferenced data to compare the number of peacekeepers deployed in an area to conflict containment in the area, comparing areas with conflicts between years (Beardsley and Gleditsch, 2015). Because of findings that peacekeepers are more likely to be deployed in more severe conflicts (Gilligan and Stedman, 2003; Gilligan and Sergenti, 2008; Fortna, 2008; Beardsley and Schmidt, 2012), the fact that they find peacekeeping does contain conflict is able to answer some endogeneity concerns about peacekeeping deployment being related to conflict severity. However, the UN may also have information about what conflicts will be easiest to resolve or mitigate that they use when making the decision to intervene. They hypothesize that peacekeeping operations may stop violence because they may deter conflicts between government and rebel forces, rather than through monitoring (Beardsley and Gleditsch, 2015). On a more granular level, data from Fjelde et al. suggests UN peacekeeping is less effective against state violence because operation requires the approval of the government, but can protect civilians against violence from rebel groups (Fjelde, Hultman and Nilsson, 2019), but Hultman argues this happens only when the intervention has a specific mandate to protect civilians (Hultman, 2010). Without that specific mandate, peacekeeping may also provide rebel groups with legitimacy, which means that if a resolution is not reached, the rebel group may pose a larger threat in the future (Beardsley and Gleditsch, 2015).

Research comparing types of peacekeeping forces tends to find that peacekeeping troops are associated with reductions in violence, but observers and monitors are not. In a comparison of different kinds of regional peacekeeping, Kim and Sandler use matching to find that only regional peacebuilding and peace enforcement missions are related to reductions in rebel-perpetrated one-sided violence, but observer, traditional, peacebuilding, and peace enforcement types of regional peacekeeping are able to reduce government-perpetrated one-sided violence. They match based on a conflict propensity score, which heavily reduces the number of observations in their dataset, so it may not be the best way to deal with endogeneity concerns (Kim and Sandler, 2022). However, research looking at where observers, monitors, and troops are sent and what factors contribute to that decision-making may be able to illuminate some reasons why troops may be more impactful.

Beardsley and Gleditsch look at civil wars from 1990 to 2010 in Africa and find that UN and regional peacekeeping forces are associated with lower government violence toward civilians, but only UN troops are associated with limiting violence against civilians perpetrated by non-state actors. They control for conflict severity and factors that affect the risk of conflict spreading because they anticipate that may influence where UN troops are sent, but they do not have a method to deal with the UN sending troops to places where their project effectiveness is higher (Bara and Hultman, 2020). In civil wars in Africa between 2000 and 2020, Kim et al. find that partnerships between regional or organization-based and UN peacekeeping are correlated with more effective missions that result in fewer battlefield casualties (Kim, Chae and Sandler, 2025). Some data indicate that non-UN peacekeeping forces tend to have proportionally fewer police and observers than troops (Bara and Hultman, 2020), so it is unclear if the relationship that Kim et al. find is just driven by the differential makeup of peacekeeping forces (Kim, Chae and Sandler, 2025), because other work has shown that the presence of police and observers is correlated with higher rates of violence (Hultman, 2010).

Research on the types of civil wars and how peacekeepers affect different types of conflicts diverges. Hendrickson finds that genocide and politicide have been less frequent after the end of the Cold War, regardless of what cutoff is used. However, when they investigate severity, the significance of results shifts based on the cutoff. When 1989 is used as the last year o f the Cold War, they find no difference in genocide and politicide severity, but using 1991 as the end date results in more severe genocides and politicides after the end of the Cold War (Hendrickson, 2022). Balcells and Kalyvas find irregular civil wars tend to last longer than other types, but conventional civil wars tend to be more lethal; however, it is unclear if this happens because rebels that are more likely to pick irregular or conventional tactics are due to factors that might influence how deadly they are or how willing they are to agree to a settlement. Balcells and Kalyvas deal with this by controlling for factors that they anticipate affect the ability to choose the tactics used by rebels and therefore the type of war, but rebels also have some ability to choose based on what they believe will be successful (Balcells and Kalyvas, 2014). When and why the UN and third-party countries or organizations choose to intervene remains an understudied aspect of interventions that may dictate how successful peacekeeping missions are capable of being.

2.2 Peacekeeping at the End of Civil War

In some instances, peacekeepers may exacerbate conflict based on the mandates they were given, but if given orders to prioritize civilians, this is not the case. Karlsrud evaluates recent UN peacekeeping missions in Mali, the Democratic Republic of the Congo, and the Central African Republic and finds they use more aggression because they were given mandates by the Security Council to combat particular groups rather than enforcing peace. This may cause the belief that the UN is taking sides to perpetrate and cause increased attacks against them (Karlsrud, 2015). Using experiments, Nomikos finds that UN forces cause individuals to believe that norm violation is more likely to be punished, so they are more willing to engage with other social groups. After UN troops withdraw, it is unclear if this willingness to engage will persist (Nomikos, 2022). Grieg and Diehl do not find evidence that leaders will experience more willingness to engage with rivals using data for interstate conflicts (from 1946-1996) and civil conflicts (from 1946-1999). In longer rivalries, peacekeeping forces reduced negotiations and the likelihood of success. In civil wars, there is no evidence that peacekeeping encourages settlements. However, this finding does suffer from some endogeneity concerns. While they use a two-step model to account for the baseline probability that a negotiation will take place and then, given that probability, the likelihood that the negotiation will be successful, they do not account for the overall likelihood of peacekeepers being sent to a conflict. Peacekeepers are more likely to be sent to worse conflicts, which could potentially explain why peacekeepers were associated with the likelihood of successful negotiations decreasing (Greig and Diehl, 2005). In general, Walter finds civil wars rarely end in negotiated settlements because a credible enforcement mechanism is usually not available. However, Walter studied conflicts only during the Cold War between 1940 and 1990, which may be due to the influence of the Cold War creating perceptions of much larger intractable differences than Civil Wars after the Cold War (Walter, 1997). I would also expect credible enforcement mechanisms to be harder to develop during the Cold War, when the US and USSR may have benefited from continuing the war, as compared to a more unipolar time when the hegemon has a larger incentive to encourage peaceful settlements.

Consent-based peacekeeping is more effective at maintaining peace than enforcement peacekeeping, Fortna finds. Consent-based peacekeeping is that which has the consent of those involved under Chapter 6 of the UN charter, whereas enforcement peacekeeping does require belligerents' consent under Chapter 7. They also show that after the Cold War, war is 84% less likely to recur if international peacekeepers are present. The number of factions involved in a civil war does not affect the ability to maintain peace, but higher death tolls do make peace harder to maintain (Fortna, 2004). In a study of African conflicts between 1992 and 2010, Kathman and Wood find that larger numbers of UN peacekeeping troops are associated with less violence against civilians, but more UN observers are correlated with violence in the two years after the end of a conflict. They aim to control for how severe the conflict was by controlling for conflict duration, the length of peace, and the number of battle deaths by month. However, this does not fix endogeneity problems with where the UN chooses to deploy peacekeepers (Kathman and Wood, 2016). Using data on the settlements of civil conflict between 1975-2005, Matanock finds civil conflicts are much less likely to remerge in settlements that allowed rebels to participate in elections and have election monitoring as a commitment device to ensure follow-through. She suggests that this indicates observers may play a role in limiting conflict recurrence (Matanock, 2017). However, it is also possible that where parties are able to agree to have elections and include their rivals, the conflict is less intractable than in conflicts where such agreements are not possible. Although this literature makes progress in identifying associations of peacekeeping troops after conflict and the sustained peace, it does not address the fact that the UN chooses where to send peacekeepers with detailed knowledge of the conflicts that cannot be controlled for in the data. It is possible this knowledge may be part of what is driving these trends as opposed to the sending of peacekeepers themselves.

This literature suggests peacekeeping can both contain civil conflict and reduce violence, especially against civilians. However, this peacekeeping effectiveness is conditional on the types of violence, the mandate given to the troops, and the number of troops. Across studies, mandates to protect civilians and the presence of troops appear to be related to reductions in violence more than the presence of monitors or observers. This research is limited by the endogenous placement of peacekeepers in particularly severe conflicts, and the UN may know additional information about the likely effectiveness of peacekeepers that the studies are unable to capture. More explicit theories and testing of how peacekeepers alter the behavior of states and rebels may be able to illuminate when peacekeepers can effectively reduce violence.

3 Theory and Hypotheses

Hypothesis 1 *Third-party military intervention increases the severity of state repression and human rights violations.*

Hypothesis 2 *Intrastate conflicts over government or territory disputes are more likely to have lower levels of state repression and worse human rights violations.*

Hypothesis 3 *Resolutions to intrastate conflicts that maintain both the government and non-state actors have more severe state repression and human rights violations.*

4 Data and Measures

4.1 First Stage: Predicting Intervention

Intrastate conflict is defined as “as a contested incompatibility that concerns government or territory or both where the use of armed force between two parties results in at least 25 battle-related deaths” (Davies, Pettersson and Öberg, 2022; Gleditsch et al., 2002) and is measured using the UCDP/Peace Research Institute Oslo (PRIO) Armed Conflict Dataset. For the purposes of this paper, conflicts are limited to intrastate conflict which requires one government actor and at least one non-state actor.

Intervention is measured using the UCDP External Support Dataset (ESD) which defines external support as party not involved in the conflict providing military or military-adjacent support to a state or non-state actor that is involved in the conflict (Meier et al., 2023). Because I am specifically interested in military intervention, I separated some variables from the ESD that include funding, other or unknown support and did not count those as a military intervention. Military intervention was limited to contributions of troops, weapons or equipment, logistics or transport, military training, intelligence sharing, access to territory for military purposes or infrastructure.

If there were humanitarian concerns was measured if the total number of refugees (combining refugees, internally displaced people, and asylees) in a country exceeded 50,000 according to counts from the United Nations High Commission for Refugees (UNHCR). This should indicate if there was a sufficient domestic problem to lead many to flee. While UNHCR records both flow and stock data of refugees, I used flow to measure contemporary problems rather than counting individuals who fled due to an issue in prior years.

I added a dummy variable for whether the conflict was during or after the Cold War. The end of the Cold War is defined as January 1st, 1989 because it was the transition from Ronald Reagan to George H. W. Bush as president of the US and it was sufficiently far after Mikhail Gorbachev's transition to power which resulted in the de-escalation of the worst of relations between the US and the USSR (Regan, 1998).

The measure for the number of bording countries comes from the Correlates of War counting a border as existing as either a direct land border or less than 150 miles of water as sharing a border (Correlates of War Project, N.d.; Gochman, 1991; Stinnett et al., 2002).

4.2 Second Stage: The Impact of Intervention

The outcome variables of physical integrity rights and human rights were compiled by Varieties of Democracy (V-Dem). Physical integrity rights include measures of freedom from slavery, arbitrary detention, and humane treatment during detention (V-Dem, 2024*b*). The human rights index includes measures of freedom from torture, slavery, politically-motivated killings, and forced labor (V-Dem, 2024*a*).

One of the independent variables measures the source of the conflict as defined by the UCDP/PRIO Armed Conflict Dataset. It has two different indicator variables for if the conflict was over territory or government control (Davies, Pettersson and Öberg, 2022; Gleditsch et al., 2002).

The second independent variable was a measure of if the conflict ended in a settlement or a complete victory. Conflicts that ended in combined victory for either side or one actor disappearing were defined as complete victory whereas conflicts that ended in peace agreements, ceasefires and fewer than 25 battle deaths were coded to be both sides still existing (Kreutz, 2010).

5 Results and Analysis

A Bayesian endogenous treatment effects model is used to account for non-random intervention. Joint estimation was used using ρ to capture unobserved characteristics that are correlated with both the likelihood of intervention and the outcome variable. Errors were correlated using: $\mathrm{corr}(u_i, \epsilon_i) = \rho /$ D_{it} is an indicator variable that takes the value 0 (1) for intrastate conflict i if in intrastate conflict i there was not (was) a military intervention. The selection stage of the model uses the formula:

$$D_i^* = Z_i'\gamma + u_i, \qquad D_i = 1(D_i^* > 0), \quad u_i \sim N(0, 1) \tag{1}$$

The outcome equation uses the following formula:

$$y_i = X_i'\beta + \delta D_i + \epsilon_i, \qquad \epsilon_i = N(0,\, \sigma_\epsilon^2) \tag{2}$$

I ran 4 chains for 4,000 iterations each (2,000 warmup, 1,000 sampling), yielding 4,000 posterior draws.
